PsqloDBC [Mac/Win]

The PostgreSQL ODBC driver can be used as a replacement of the Windows ODBC drivers provided by Microsoft. psqloDBC can be used with the PostgreSQL ODBC driver that has been included in the Fedora Core 5 distribution by default. It should be noted that the psqloDBC driver provides support for all the PostgreSQL interfaces, not just those related to the SQL-ODBC standard. A list of supported PostgreSQL interfaces are available in the PostgreSQL ODBC documentation. Data Provider Usage psqloDBC helps to improve the connection and statement usage when working with the PostgreSQL database management system. Any SQL statement that does not require specific type conversion can be executed using this driver. It is important to note that the PostgreSQL database schema supports the execution of DDL statements (i.e. table creation, data type creation, index creation, etc.), which makes it possible to create the database structure and the tables at once. This is the main reason that makes the ODBC driver provided by PostgreSQL so useful. Other uses can include: mapping relational queries to the database, using native Windows ODBC drivers with the PostgreSQL database management system.

PsqloDBC Features The following features are available: Prepared statements Caching of prepared statements Restricted queries Customizable result sets Access to table data Query results can be parsed Custom queries Batch execution Transactions Binary data handling Full SQL standard support Example Database migration with psqloDBC and Fedora Core 5 There are a few things that you should be aware of when migrating the database with the PostgreSQL database management system. First of all, you must be sure that the new server supports the SQL-ODBC standard, otherwise the table data migration might be incomplete. In order to determine whether or not the SQL-ODBC standard is supported, the PostgreSQL ODBC documentation must be consulted. When you are sure that the database server supports the ODBC standard, you can proceed to the first step of the migration process, which consists of copying the old data into the new database, using the psqloDBC driver: % cp myDataBase/myTable.frm myDataBase/myTable.frm.old % mv myDataBase/myTable.frm myDataBase/myTable.frm.new psqloDBC is already included in the Fedora Core 5 distribution

This software solution can help advanced computer users set up connections that can be used by every single application in their system via the native ODBC Data Source Administrator. Once the connection has been successfully configured, it will help them work with pieces of data stored within the PostgreSQL server both quickly and directly. The connection strings can be observed and studied in the following section: When a connection has been configured, it will show the following: Connection
